

The Truth About Great Tans And Tanning With Spray - Discover Convenient Solutions Now

Thousands of people have come to replace natural sun tan with spray tanning, especially since thus you can benefit from a great honey-like skin all year round. It is both rewarding and revitalizing to look in the mirror and admire a beautiful tan when the temperature outside is below freezing point. Is there an advantage of spray tanning over regular indoor tanning? The controversy of tanning services is that they are not 100% safe since they still imply exposure to UVA and UVB. The action of the ultraviolets could be one of the most dangerous, since even in controlled environment the hazard of developing skin cancer remains pretty high.

Spray tanning options are offered by a lot of manufacturers specialized in this market sector. Most items usually include the message "easy to apply evenly" but if the quality is not very high, there could be disadvantages to the use of spray tanning. Nevertheless, speaking in ideal terms, spray tanning allows you to reach spots that are much more difficult to massage with a skin lotion: this is the case of the shoulder blades for instance or the lower back areas. Moreover, the chance of getting tan lines and color streaks is lower with spray tanning as compared with other products.

Then, there is a lot less "hands on" application required in spray tanning particularly since the pigmentation substances in the chemical blend of the tanner proves very difficult to wash off the hands. Then, spray tanning solutions have a better completion rate than gels, foams and lotions which means that you can get dressed immediately after applying the sun-free tanning product. One highly new idea is represented by the invention of "airbrushing" booths that spray bronzing substances neatly on the entire body. This kind of service is usually available in very prestigious treatment salons.

Only use quality tanning skin products that allow for a correct and healthy skin passage of the ultraviolets and thus contribute to the tanning in itself. Once the health concerns are settled, you can carry on to uncover more of the indoor tanning tips that help you make the tan last longer. How to deal with exfoliation? How to enjoy more of your tan? And last but not least, how to prevent the skin from turning dry or flaky? These are all well documented in magazines and on lots of web pages online.

The bad part about "airbrush" spray tanning is that cleaning after the spray application could be pretty difficult: fingernails for instance are the worst to clean if you do not put something protective during the self-tanning process. The effect of spray tanning usually remains on the skin for about five to seven days particularly if the skin is moist when you apply the tanner. This means that if the skin undergoes a preparation process before spray tanning then the results will be more rewarding and longer lasting. Enjoy it!
